^aCritical molar volumes can be obtained from $v_{\rm cr} = Z_{\rm cr} R T_{\rm cr}/p_{\rm cr}$, and critical densities from $\rho_{\rm cr} = M/v_{\rm cr}$ (e.g. for acetone $v_{\rm cr} = 209 \cdot 10^{-6}$ m³/mol and $\rho_{\rm cr} = 351$ kg/m³.

^bThermal capacities of monoatomic gases do not change with temperature, but for polyatomic gases it increases more the more atoms has the molecule.

d Dynamic viscosity of gases increases with the square root of temperature, and do not change with pressure. Kinematic viscosity $v = \mu/\rho$.

^e Bubble point.

^f Sublimation point.

^g Pseudo-critical point (Kay's model).

h Most gas properties vary a lot near the critical point, what may be here the case; e.g., for CO₂ gas at 288 K and 100 kPa, thermal capacity at constant pressure is c_p =840 J/(kg·K), growing at constant T=288 K from c_p =833 J/(kg·K) at very low pressure, to c_p =3010 J/(kg·K) at the saturation pressure (5063 kPa). Thermal capacity in the ideal gas limit (p→0) varies almost linearly (e.g. c_p =753 J/(kg·K) at the triple-point temperature, c_p =850 J/(kg·K) at the critical-point temperature).

Mercury is obtained by oxidation of cinnabar at some 600 °C and vapour condensation. Mercury vapour should not exceed 0.1 mg/m³ in breathing air (notice that saturated air at 20 °C already contains more than that

limit.

Nitrogen dioxide, NO₂, is a very toxic brown gas at normal conditions (but readily condensable, T_b =21.3 °C). All nitrogen oxides slowly decomposing to nitrogen and oxygen, making it difficult to keep them in pure state; besides, NO₂ is paramagnetic, but readily dimerises to dinitrogen tetroxide, N₂O₄, a diamagnetic pale-yellow or colourless gas with double density than NO₂ (e.g. when heating from above an ampoule containing NO₂, some N₂O₄ is formed at the top (2NO₂(g)=N₂O₄(g)+57 kJ/mol), which can be seen sinking to the bottom because of buoyancy). The NO₂/N₂O₄ equilibrium depends on temperature, NO₂ being favoured at

Thermal conductivity of gases increases with the square root of temperature, decreases with the square root of molar mass, and do not change with pressure. Thermal diffusivity $a = k/(\rho c_p)$. According to simple generalised transport theory in gases, thermal diffusivity, mass diffusivity and kinematic viscosity of gases have the same values.

high temperatures and N_2O_4 at low temperatures; when condensing (at 21.3 °C at 100 kPa), most of the liquid is N_2O_4 which is colourless or pale brownish, and if solidified (at -11.2 °C) a white solid appears. The liquid N_2O_4 is a hypergolic propellant that spontaneously reacts upon contact with various forms of hydrazine, which

makes the pair a popular bipropellant for spacecraft rockets.

^k Di-nitrogen oxide, N₂O, also known as nitrous oxide (NO is nitric oxide), or nitrogen hemi-oxide, or nitrogen protoxide, or laughing gas, is used in respiratory anaesthesia since the pioneering trials of Sir Humphrey Davy in 1789 shortly after its discovery by J. Prietsley in 1772, as a non-flammable non-ozone-depleting propellant in aerosol cans, and as a fuel additive to enhance combustion (it liberates oxygen; if added as compressed liquid in the intake manifold, it greatly increases fuel load). It has a global warming potential (GWP) of 300 times that of CO₂, being the third contributor to anthropogenic GWP, after CO₂ and CH₄.

¹ R410A is a near-azeotropic mixture of R32 (diffuoromethane, CH₂F₂) and R125 (pentafluoroethane, CHF₂CF₃), 50/50 by weight (70/30 molar), which can be approximated as a pure substance. The critical point of a binary mixture is defined as the point where $\frac{\partial^2 g}{\partial x^2}$ and $\frac{\partial^3 g}{\partial x^3}$ are simultaneously zero, where g is the

Gibbs energy and x is the mole fraction of a component.

m Sulfur hexafluoride is a synthetic gas used as insulator for electrical equipment (breakdown potential three times larger than air, and as a fluorine source for edging in the electronics industry. It is a non-flammable, non-toxic gas, which decomposes at 750 K; it has low water solubility, and a very large IR absortance (it is the most potent greenhouse gas, GWP=22 000), what has been used as a trace gas for gas-leakage detection.

ⁿ Uranium hexafluoride, perhaps the heaviest simple molecule, is the only uranium compound presently used in industrially enrichment of U-235, both on gas diffusion and on gas centrifugation processes. At room

conditions, it is a white crystalline solid with a high vapour pressure (p_v =11 kPa at 20 °C).

^p The boiling point of water at 100 kPa is T_b =372.75±0.02 K (99.60±0.02 °C), whereas at 101.325 kPa (1 atm) it is 373.12±0.02 K (99.97±0.02 °C).
